

The problem: Agents need to share data

Introduction

How do agents communicate?

In part 2, you saw agents in workflows. But how does one agent use the output of another?

The answer: Shared session state.

- Agent A writes its output to state
- Agent B reads that output from state
- This is how data flows between agents

From ADK documentation

“Agents can communicate by reading from and writing to the shared session state. This is particularly useful in workflow agents where sequential or parallel agents need to share data.”

The problem: Agents need to share data

Consider a content pipeline:

```
Python
# Agent 1 researches a topic
# Agent 2 needs to use that research to write

# How does the writer get the researcher's output?
```

Without a communication mechanism, each agent works in isolation.
